Development of Economic and Proportional Outcomes of
Provincial Nominee Program Candidates, Province to Province

Introduction

Provincial Nominee Programs (PNPs) are Canadian immigrant programs run by provinces or territories independent of the federal government. A major goal of PNPs is “regionalization”, a nation-wide push to increase populations outside of major metropolitans and especially outside the three biggest provinces of Canada (Ontario, Quebec, and British Columbia). PNPs target economic immigrants, bringing in 35% of all economic migrants in Canada in 2022 (Picot et al., 2024, p. 2).

What constitutes an ideal candidate depends heavily on the program and streams within the program. For instance, PNPs do not only target professional or technical foreign talent. PNPs are unique from federal programs for their “capacity to select low-skilled workers” (Xhardez and Tanguay, 2024, p. 14). PNPs have recently demonstrated a movement away from “human capital”-based immigration programs (language skills, job experience, qualifications) and into immigration programs based on relevant demand (previous work experience in Canada, waiting job offer). The reason for the shift is to resolve difficulties of immigrant integration (Lewis, 2010). As Lewis finds in his study of Manitoba PNPs, “the rapid increase in immigration to Manitoba, reduced funding, and multiple parties charged with resettlement”, including

ethnocultural welcome organizations, community volunteers, and employers, “[has resulted in] mismatches between nominees’ skills and constantly changing job markets have recently become more pronounced”; Lewis also cites a 2002 survey of nominees in which 50% were not working within their expertise (2010, p. 250). With guaranteed demand or, better yet, a guaranteed placement, the nominee’s intended purpose in the province – to stimulate the economy with their skills – will have a higher likelihood of mutual fulfilment for the nominee and the province.

But with increased regionalization and more specialized nominee requirements, has there been an empirical improvement in the economic standing of immigrants who are products of novel systems? In this study, I will compare the wages of recent immigrants (landed 10 or less years before study; 2014-24), older immigrants (landed more than 10 years before study; <2014), and non-immigrants to make inferences on whether new immigrants are more adaptable than older immigrants of older systems. The point of separation between recent and older immigrant categories is 2014, representing the period immigrant programs moved away from human capital in the 2000s (Xhardez and Tanguay 2024).

Because of limits in data, there is no direct way to differentiate between the impact of integration and the immigration system. The dataset also only surveyed the employed, so unemployment rates couldn’t be factored in. Notable impacts will be determined by whether working new immigrants are faring significantly better than working old immigrants, and whether they are on the level of or above working non-immigrants. This would indicate that new immigrants began their residence in Canada as intended – to work in their intended field, with a wage comparable to the native population, in a lower-population province.

Method

This study uses the Canadian Government's Labour Force Survey (LFS) dataset, conducted January 2024. LFS is a random sample of Canadian residents aged 15-64 who are employed and were at work in the week before the survey. The survey uses this week as the reference week which data is collected. The set collected responses from 48,745 respondents from every province in Canada.

This study applies multiple linear regression analysis and descriptive statistics to the LFS 2024 dataset in order to compare the usual hourly wages of non-immigrants, recent immigrants, and older immigrants across provinces. Statistically significant findings point to possible impacts of novel immigrant programs.

Dependent variable

The dependent variable measured is usual hourly wages at main job (measured in CAD, Canadian Dollars). For the purposes of this study, all analysis is focused on activity at the worker's main job. Mean usual hourly wages is \$34.48 and the median is \$29.81, indicating the common positive skew associated with income.

Independent variables

Fifteen variables were used in this analysis: age group, marriage status, student status, sex, highest education level, immigrant status, province of residence, occupation at main job, class of worker at main job (public/private), size of firm, whether they worked overtime, amount of unpaid hours, tenure, union status, whether they were absent part of the week, and usual hours worked per week.

The majority of these variables are used as controls. The focus of this study is on immigrant status, province of residence, and occupation at main job.

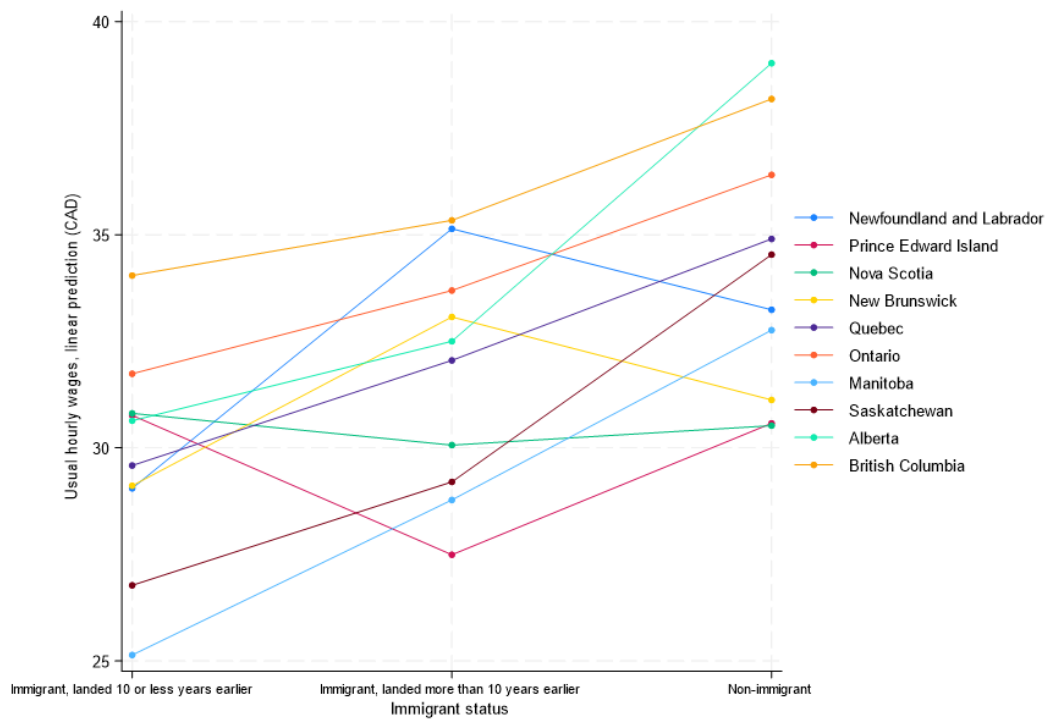

Time variables (overtime, unpaid hours, absence, and usual hours worked) were selected for this analysis because a relationship between usual hours worked and usual hourly wages was indicated by a scatter plot of the two variables (Graph 2A).

The dataset didn't collect some key data I believe would've improved my analysis, including race, ethnicity, continuous count of years since immigration, national origin of immigrants, whether immigrant respondents were working in intended occupation, and last province of residence (and time since move, if applicable). These variables could have tested the issues (ethnocultural divide, occupation discrepancy, two-step model, outside party reliance, immigrant retention) described by literature on PNPs (Lewis, 2010; Xhardez and Tanguay, 2024).

Notes on the regression equation

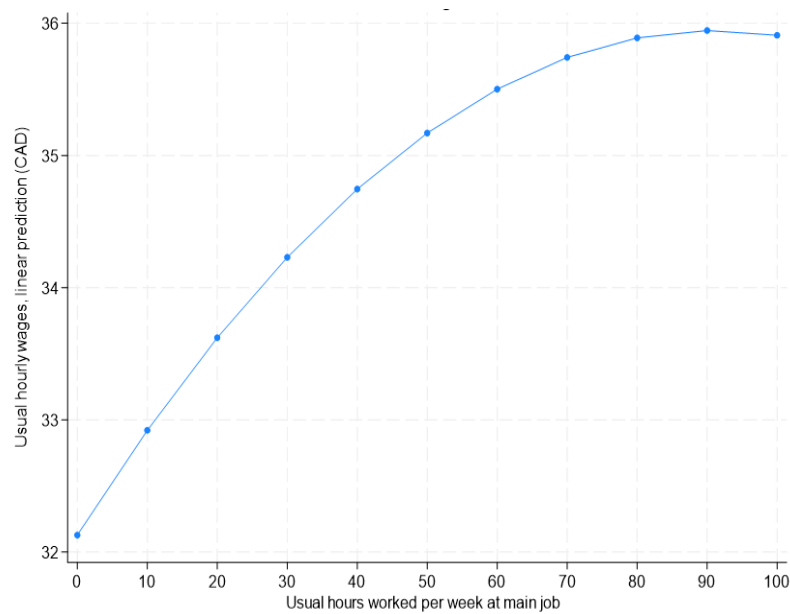

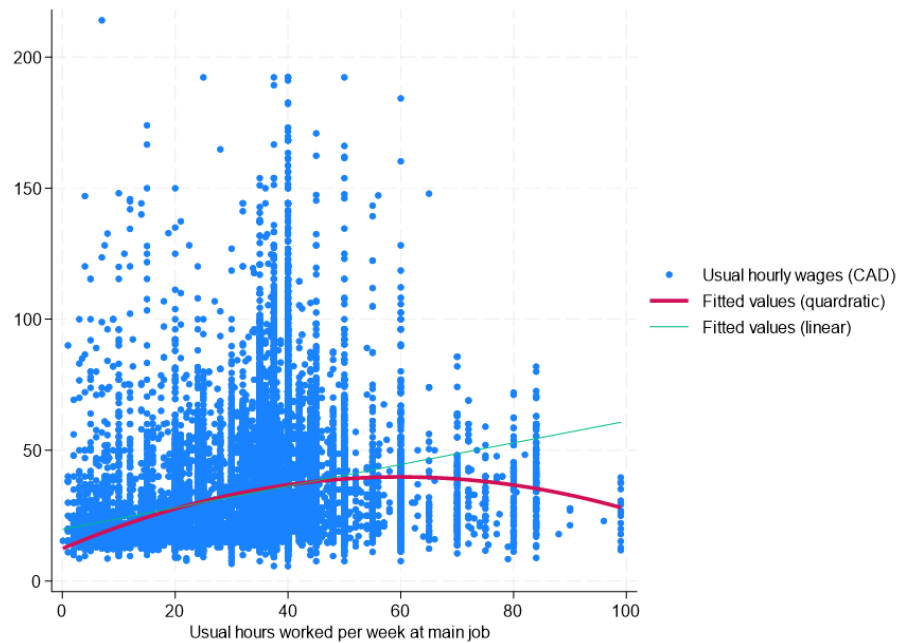

An interaction term accounts for an additivity issue between immigrant status and province. The literature indicates that different provinces acclimate immigrants at different rates, thus leading to income levels more equivalent to the non-immigrant population more quickly (Lewis, 2010). This is supported by the different slopes for each province in Graph 1, the margins plot predicting usual hourly wages mapped out to immigrant status.

Graph 1: Margins Plot Predicting Hourly Wage for Immigrant Status (x-axis) and Province of Residence (line legend on right)

A quadratic term accounts for the non-linear relationship between usual hourly wages and usual hours worked in a week. This relation is observed in a preliminary scatter plot between the two variables (Graph 2A) and is accounted for in a post-regression margins plot with a similar quadratic slope (Graph 2B).

Graph 2: (A) Pre-regression Scatter Plot, for Usual Hours Worked to Usual Hourly Pay (CAD) – with a Linear Line of Best Fit (Green) and Quadratic Line of Best Fit (Red);
(B) Post-regression Margins Plot, for the Same Variables

Results

Table 1 presents the effect of all independent variables on the dependent variable, usual hourly wage, with unstandardized beta coefficients and associated standard errors. With this regression analysis, 43.9% of variance in the dependent variable is accounted for.

There is a stark difference in the hourly wages of new immigrants in the Atlantic provinces and other provinces. Netting for other independent variables, new immigrants in Ontario on average make \$4.67 less per hour than non-immigrants while older immigrants in Ontario make \$2.71 less per hour than non-immigrants, which is \$1.96 more than new immigrants (all $p < 0.001$). Provinces with PNP intake counts similar to Ontario are Manitoba, Alberta, British Columbia, and (to a lesser degree) Saskatchewan (Picot et al., 2024, p. 5). According to our regression equation, recent immigrants in prairie provinces (Manitoba, Alberta, and Saskatchewan) receive significantly less hourly wages than non-immigrants. In Manitoba, recent immigrants get \$2.95 less per hour than non-immigrants compared to Ontario non-immigrant salaries; in Alberta, it's \$3.72 less; in Saskatchewan, \$3.09 less ($p < 0.001$). Older immigrants receive similar smaller rates. This indicates a lack of economic integration even after more than ten years in Canada. A relationship between immigrant status and hourly wages within British Columbia and Quebec could not be proven.

In the Atlantic provinces, however, new immigrants fare very well. Non-immigrants in Prince Edward Island, Nova Scotia, and New Brunswick make significantly less than non-immigrants in Ontario (they have the lowest range in comparison to Ontarians, in the range of \$5.28-5.88 less). Non-immigrants in Newfoundland and Labrador do slightly better, making \$3.61 less per hour than non-immigrants in Ontario. In comparison, new immigrants in Prince Edward Island only make \$0.98 less per hour than non-immigrants in Ontario. New immigrants

in Nova Scotia the figure is \$0.93 less, in New Brunswick the figure is \$2.63 less. The wages of older immigrants in these provinces can't be determined, except for in New Brunswick in which older immigrants make only \$0.62 less per hour than non-migrants in Ontario. Older immigrants in Newfoundland and Labrador make more than non-immigrants in Ontario, at about \$1.45 more per hour.

The Atlantic provinces (Newfoundland and Labrador, Prince Edward Island, Nova Scotia, and New Brunswick) have lower proportions of immigrants overall compared to other provinces, however they are the only provinces, other than Saskatchewan, that have a higher proportion of new immigrants than old immigrants (see Table 2). This may indicate a low retention rate, an increasing intake rate, or both. Both hypotheses are supported by other research (Picot et al., 2024).

I don't believe immigrant retention is the primary influencing factor for a few reasons. First, the "immigrant status" variable groups immigrants over a wide range of years (a decade), so the category includes those who have settled. Second, immigrants make about as much or more in Atlantic provinces as non-immigrants make in Ontario. There is a significant economic incentive to remain in Atlantic provinces.

According to Table 3 (bivariate table of occupation at main job x province), there is a higher rate (1-3% difference compared to overall rate) of health workers in the Atlantic provinces; there are also more sales and service workers in Nova Scotia and New Brunswick, and more trades, transport, and equipment operator workers in Newfoundland and Labrador and PEI. In the expanded multivariate table also segmenting immigrant status (Appendix 1), although immigrants overall are less represented, new immigrants in Atlantic provinces are often more comparable to the overall proportion of new immigrants in an occupation than older immigrants.

For example, new immigrants make up 9.27% of health workers in Nova Scotia and 7.96% in New Brunswick, respectively only 0.37 and 1.68 percentage points lower than the overall proportion of new immigrants health workers. In comparison, older immigrants make up 4.42% of health workers in Nova Scotia and 2.42% in New Brunswick – respectively 12.23 and 14.23 percent points lower than the overall proportion of 16.65%. Additionally, the proportion of health workers NS:total and NB:total both have a difference of 0.02 proportional points or less between new immigrants and non-immigrants; this proportion is more than 0.05 points between older immigrants and non-immigrants. This is an overall trend for most occupations within the Atlantic provinces. In comparison, all other provinces have a higher proportion of older immigrant health workers than newer – in the case of Ontario, the proportion of older immigrant health workers in total is far larger than for non-immigrants (40.58% for older migrants vs 26.29% for non-immigrants).

Conclusion

Comparing the proportional and wage trends of new immigrants in Atlantic provinces to other immigrant statuses and other provinces, there is an indication of a growing new immigrant population in Atlantic provinces. This aligns with the increase of economic migrants accepted by provincial nominee programs in these provinces in the last 10 years. In 2019, Nova Scotia accepted a high of about 3,500 economic migrants through PNPs – in 2009, they accepted just under 1,000 nominees via PNPs (Picot et al., 2024, p. 5). Though other provinces nominate more candidates through PNPs, these provinces show an older immigrant lean in the province x occupation x immigrant status multivariate table (Appendix 1) which does not favor newer immigrants. This indicates a stronger focus on new immigrants by Atlantic provinces that aligns

with a stronger focus on PNPs, different from other provinces. Along with evidence that Atlantic provinces have a higher proportion of new immigrants than older immigrants, the hourly wages of new immigrants that are favourably comparable to one of the most fortunate populations in Canada, non-immigrant Ontarians, point to an increase in the favorability of new immigrants from Provincial Nominee Programs.
